CSE 569 Homework #3

Total 3 points Due Thursday, Nov. 7 by 11:59pm.

Problem 1. (From Problem 3 of Chapter 4 in the textbook)

Let $p(x) \sim U(0, a)$ be uniform from 0 to a, and let a Parzen window be defined as $\varphi(x) = e^{-x}$ for x > 0 and 0 for $x \le 0$.

(a) Show that the mean of such a Parzen-window estimate is given by

$$\bar{p}_n(x) = \begin{cases} 0 & x < 0\\ \frac{1}{a}(1 - e^{-x/h_n}) & 0 \le x \le a\\ \frac{1}{a}(e^{a/h_n} - 1)e^{-x/h_n} & a \le x. \end{cases}$$

- (b) Plot $\bar{p}_n(x)$ versus x for a=1 and $h_n=1,1/4$, and 1/16.
- (c) How small does h_n have to be to have less than one percent bias over 99 percent of the range 0 < x < a?
- (d) Find h_n for this condition if a = 1, and plot $\bar{p}_n(x)$ in the range $0 \le x \le 0.05$.

Problem 2. Consider a 1-dimensional 2-class classification problem with class-conditionals as follows:

$$p(x|\omega_1) = \begin{cases} 2x, & x \in [0, 1] \\ 0, & otherwise \end{cases}$$

$$p(x|\omega_2) = \begin{cases} 2(1-x), & x \in [0, 1] \\ 0, & otherwise \end{cases}$$

Assume that the priors are equal, i.e., $P(\omega_1) = P(\omega_2) = 0.5$.

- (a) What is the Bayesian decision boundary for doing minimum error rate classification? What is the corresponding Bayes error?
- (b) You are given two training samples: x_1 from ω_1 and x_2 from ω_2 . Also, we know $x_1 < x_2$. Find the nearest-neighbor (NN) decision rule for classifying any new data point x. What is the probability of error for this NN classifier? (Note: for this Part (b), you are given a fixed training set, i.e., you view x_1 and x_2 as some given, fixed values.)
- (c) More generally, suppose we randomly select a single point x_1 from ω_1 and a single point x_2 from ω_2 , and create an NN classifier. Consider using this NN classifier to classify a random sample drawn from ω_1 . What is the probability of error?

Problem 3. Prove that the Voronoi cells induced by the nearest-neighbor algorithm must always be convex. That is, for any two points \mathbf{x}_1 and \mathbf{x}_2 in a cell, all points on the line linking \mathbf{x}_1 and \mathbf{x}_2 must also lie in the cell.

Problem 4. Computer Exercise. [Review 06-Feature-Selection-Intro.pdf before working on this question. This question is essentially a simulation of the example given in Slides 11. You will need to write some code for doing part of this exercise. Include your code in the submission.]

Do the following exercise three times, with n=20 the first time, n=100 the second time, and n=600 the third time. (And feel free to try with other numbers too.)

- (1) Generate the first set D_1 of n samples from the normal distribution N(1, 1). Generate the second set D_2 of n samples from the normal distribution N(1.5, 1).
- (2) Assume D_1 is a set of i.i.d. samples of certain feature for Class 1 in a two-class problem, and accordingly D_2 is a set of i.i.d. samples of the feature for Class 2. Test if we should accept the hypothesis that the means of this feature for the two classes are the same for a given significant level 0.05.
